Abstract/Summary of Results and Conclusions

Broadleaf and grassy weeds are problematic in cereal production, posing challenges to growers in the selection of effective herbicides. Many growers are interested in combining different treatments in one tank mixture in order to cut costs and labor. However, when mixing different herbicides, new concerns about crop safety call for more research in tank mixture options. Research was conducted in the San Joaquin Valley in the 2012 production season, generally focusing on the interactions between several different herbicides at varying rates, with and without a surfactant, when applied as a tank mixture. After trials were completed, it was noted that no treatment in any trial caused severe or lasting injury, and what little amount of injury there was did not significantly vary between trials.

Overall, tank mixtures that included both Axial and Express with varying amounts of MCPA Amine, Clarity, and Induce provided excellent control of both grasses and broadleaf weeds. Express alone does not control grasses and Axial alone does not control broadleaves. The herbicide Simplicity without the surfactant Induce was not as effective at controlling Italian ryegrass (*Lolium perenne*) as other treatments, and only the tank mix of Osprey+AMS+Induce controlled ripgut brome (*Bromus diandrus*) and volunteer barley(*Hordeum vulgare*). All of the treatments gave excellent control of common chickweed (*Stellaria media*) except ET+NIS, Shark+AMS+NIS, and Axial alone. Control of coast fiddleneck (*Amsinckia menziesii*), shepherd's purse (*Capsella bursa-pastoris*), London rocket (*Sisymbrium irio*), and common groundsel (*Senecio vulgaris*) varied widely across all treatments that did not primarily consist of Express+Shark.

Introduction and Objectives

Wheat is one of the most important crops throughout California, and for small grain producers, weeds pose a significant problem that nearly always requires treatment. Although broadleaf and grassy weeds can be reduced by crop rotation and tillage, these cultural practices are being replaced by greater dependence on herbicides. In addition, this dependence raised concern about the evolution of herbicide-resistant weeds.

Recently, several new small grain herbicides have been released to the market and have been successfully used in different parts of the country. Growers in California are hesitant to use these herbicides because they are unsure about the crop injury that could result from a chemical that they are unfamiliar with. Research in this area of the country was necessary to evaluate the safety of these new herbicides and to provide confidence for California growers.

Materials and Methods

This project consists of four field experiments conducted in the San Joaquin Valley and one in Tule Lake. Trials were conducted with grower cooperators and at WSREC and IREC field stations to evaluate the efficacy of the herbicides along with crop injury. The experimental design was a randomized block. In every trial, the plots were eight by twenty-five feet and herbicides were applied with CO₂ backpack sprayers with 8002 flat fan nozzles. The tank-mixture and the broadleaf control studies in Visalia were planted on January 13, 2012, and herbicides were applied at 16.8 GPA and 30 PSI to wheat at the 4-8 leaf stage. The grass control study in Visalia had Redwing wheat planted on February 6, 2012, with herbicides applied at 15 GPA and 30 PSI to the 3-4 leaf stage. The broadleaf control study at WSREC used PR 1404 wheat which was planted on January 31, 2012 with herbicides applied at 15 GPA and 30 PSI to the 3-6 leaf stage. Treatments varied between trials, but included the herbicides Express, Osprey, Axial, MCPA Amine, ET, NAI 1295-2, Venue, Shark, Clarity, Simplicity, and 2,4-D, surfactants Induce and Agridex, and ammonium sulfate. Evaluations were taken between 1 and 15 weeks after treatment.

Budget: Funding was used almost entirely for employee labor/benefits with a small amount used for supplies.

Results

When comparing treatments, it was noted that tank mixtures that included both Axial and Express with varying amounts of MCPA Amine, Clarity, and Induce provided excellent control of both grasses and broadleaf weeds, but Express alone does not control grasses and Axial alone does not control broadleaves (Tables 1, 2, 3, 4, 5). In the broadleaf study at WSREC, Shark+Induce+AMS and ET+Induce were the only treatments that did not give excellent control of common chickweed (*Stellaria media*), and instead gave fair - good control (Table 7). The only treatments that gave excellent control of coast fiddleneck (*Amsinckia menziesii*), shepherd's purse (*Capsella bursa-pastoris*), London rocket (*Sisymbrium irio*), and common groundsel (*Senecio vulgaris*) included Shark+Express at varying rates (Tables 8, 9, 10, 11). The herbicide Simplicity without the surfactant Induce was not as effective at controlling Italian ryegrass (*Lolium perenne*) as other treatments, and only the tank mix of Osprey+AMS+Induce controlled ripgut brome (*Bromus diandrus*) and volunteer barley (*Hordeum vulgare*) (Tables 13, 14, 16). All of the treatments in the grass control study gave excellent control of common chickweed (Table 15). In the tank mixture study, all mixtures gave excellent control of all weeds present (Tables 18, 19, 20, 21). No treatment in any trial resulted in any lasting injury to wheat (*Triticum*), and whatever small amounts of injury that there was did not vary significantly between trials (Tables 6, 12, 17, 22).

Discussion, Conclusions and Recommendations

The low incidence of injury suggests that there is minimal if any antagonism between herbicides used in these tank mixtures. There appears to be adequate safety in all treatments. Research should continue to further verify the safety of new wheat herbicides and when possible to work with chemical companies and DPR to change some labels to allow more flexibility with herbicide application using tank mixes.
